

Residential Course on Clinical Pharmacology of Antiretrovirals 2005 – 2015

 Laboratorio di
Farmacologia Clinica
e Farmacogenetica

Gianni Di Perri

Clinica di Malattie Infettive
Università degli Studi di Torino

Ospedale Amedeo di Savoia

- This project took place following the development of a Laboratory of Pharmacokinetics inside the Infectious Diseases Unit of the University of Torino
- Based on the consideration that Torino hosted the third largest Italian HIV case series per single clinical center, and that antiretroviral therapy should have been administered for the entire life, we decided to devote ourselves to the study of clinical pharmacology of antiretrovirals in order to try to better understand what we were doing to our patients
- The Residential Course on Clinical Pharmacology of Antiretrovirals has grown up in parallel with our genuine enthusiasm of working in such rapidly developing field, in which most of the novelties we have seen in the last 20 years really contributed to a longer and better life for our Patients
- The Residential Course in Clinical Pharmacology of Antiretrovirals, further to be a unique opportunity for us to learn from our Speakers and Participants, it's a sort of celebration of our happiness to have You All here, to testify how good the idea was and still is, to annually assemble those, pharmacologists, clinicians and non-clinicians, who share the same passion for this special setting

Although the acknowledgments are usually done at the end, please let me anticipate my truly sincere gratitude to two particular Friends and Collaborators Who actually made their best efforts to make this project working....

Prof. Stefano Bonora

Dr. Antonio D'Avolio

..together with Mauro Sciandra...

.....but at the very beginning, the very first move of this project was made together with...

Dr. Marta Boffito

Dr. Margherita Bracchi

..Who acted as pioneer in establishing our partnership with the David Back's Pharmacology Group in Liverpool before migrating to the Chelsea HIV Unit in London..... We are still sad but truly proud as well!

...and on this line I am also very grateful to Dr. Lorena Baietto (PhD) for Her hard work in the Lab and the efforts She has made in teaching to students, technicians and postgraduates....

Dr. Lorena Baietto

More recently we also had the privilege to work with Dr. Marco Siccardi (PhD), Who graduated with us, and after having developed remarkable technical skills and successful scientific innovation also migrated to the UK where He joined the Pharmacology Group in Liverpool.

We feel sadly proud, again....

Anti-HIV Therapy Treatment History

THE INHIBITORY QUOTIENT*

HAROLD C. NEU, M.D.

Chief, Division of Infectious Diseases

PAUL D. ELLNER, Ph.D.

Director, Clinical Microbiology Services

Columbia University College of Physicians and Surgeons
New York, New York

THE past few years have seen many improvements in methods to determine the susceptibility of microorganisms to different antibacterial agents. Although most physicians continue to speak of bacteria as susceptible or resistant to an antibiotic, the use of minimal inhibitory concentrations (MICs) has become increasingly common when dealing with nosocomial pathogens which often resist older penicillins and cephalosporins. This paper will evaluate the meaning of inhibitory concentrations and peak serum concentrations as they relate to the use of antimicrobial agents in outpatient settings.¹

THE INHIBITORY CONCENTRATION

What is an inhibitory concentration? The minimum inhibitory concentration (MIC) of an antibiotic is that amount of antimicrobial agent which will inhibit the visible growth of a microorganism, as measured by the eyes or by a machine using light scattering. The MIC is determined with generally agreed-upon numbers of bacteria, 10^4 or 10^5 colony-forming units (CFU), using a standard broth or agar medium which contains antibiotic in twofold differing concentrations. The minimal bactericidal concentration (MBC) is the lowest concentration of drug that kills 99.9% of the organisms. This is determined by removing clear fluid from tubes or wells in a plate and placing the fluid onto agar plates. Bacteria which were inhibited but not killed will grow. Although many factors, such as size of inoculum, type of medium, cation content, osmolality, and aerobic

*Presented as part of a Symposium on Recent Developments in Oral Antibiotic Therapy: Bacampicillin Update held by the Section on Pediatrics and the Section on Medicine of the New York Academy of Medicine December 19, 1982. This symposium was supported by a grant from Roerig, division of Pfizer Pharmaceuticals.

$$\text{Inhibitory quotient (IQ)} = \frac{\text{Average peak level achievable in target tissue or fluid}^*}{\text{Minimum inhibitory concentration (MIC) of pathogen}}$$

Fig. 1. Calculating the inhibitory quotient.

concentration data that we called the inhibitory quotient (IQ).³ Calculated as shown in Figure 1, the IQ is a number that indicates the multiple of the MIC expected with the lowest dosage of an antimicrobial agent. Examples of typical MIC data are shown in Table I and typical blood levels in Table II.

We initially applied the IQ system to parenteral therapy, but it also lends itself to use with oral agents. This method permits determination of MICs of bacterial isolates using either commercially frozen microdilution plates or such optical devices as the Autobac®. Antimicrobial agents selected for testing are those which would be used against the organisms. Concentrations used in testing are based upon those necessary to separate isolates which would be inhibited or killed from those which would survive.

In our institution, values for average peak serum levels of antibiotics are stored in a computer. Antibiotic blood levels chosen for intravenous use are those that would reflect the level achieved at the end of 20 to 30 minute infusions, while oral levels are based on the peaks known from studies in normal individuals, and may reflect a level at one hour or two hours, depending upon absorption kinetics of the particular antibiotic. Urine concentrations chosen are those found in the urine during the first several hours after administration of the drug. Certainly urine concentrations of some agents may be markedly depressed if the individual has impaired renal function with a glomerular filtration rate below 30 ml/mm and the agent in question is cleared primarily by glomerular filtration. Levels in cerebrospinal fluid, which of course apply only to parenteral therapy, are based on the much higher doses used to treat meningitis and on the presence of meningeal inflammation.

In each instance, inhibitory quotients reported to a physician are those appropriate to the body site of the specimen, such as serum, urine, bile, or

*Lung is considered part of the central body compartment due to its high blood flow and hence the serum level is used.

How to quantify the “power” or “potency” of our PK exposure?

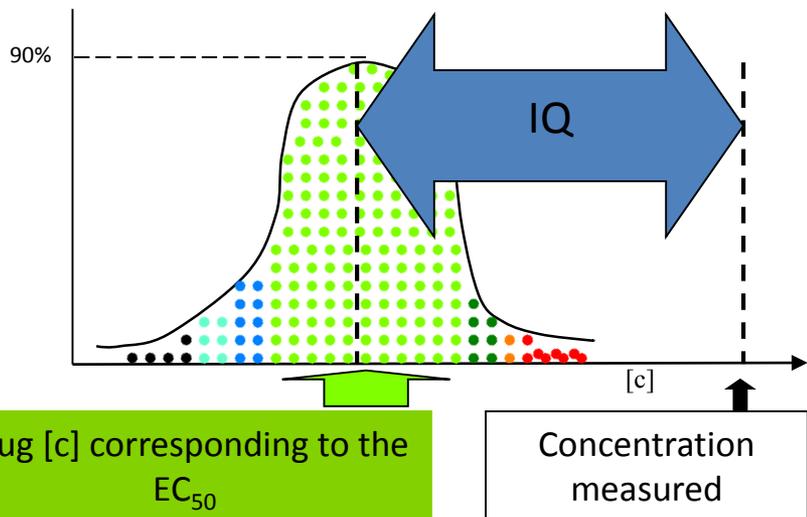

$$GIQ = \frac{\text{Plasma } C_{\text{trough}}}{\text{n. of relevant mutations}}$$

$$IQ = \frac{\text{Pk exposure}}{\text{Viral susceptibility}}$$

$$NIQ = \frac{\text{Patient IQ}}{\text{Reference IQ}}$$

$$PIQ = \frac{\text{Plasma } C_{\text{trough}}}{IC_{50-90}}$$

$$VIQ = \frac{\text{Plasma } C_{\text{trough}}}{\text{Virtual Phenotype}}$$

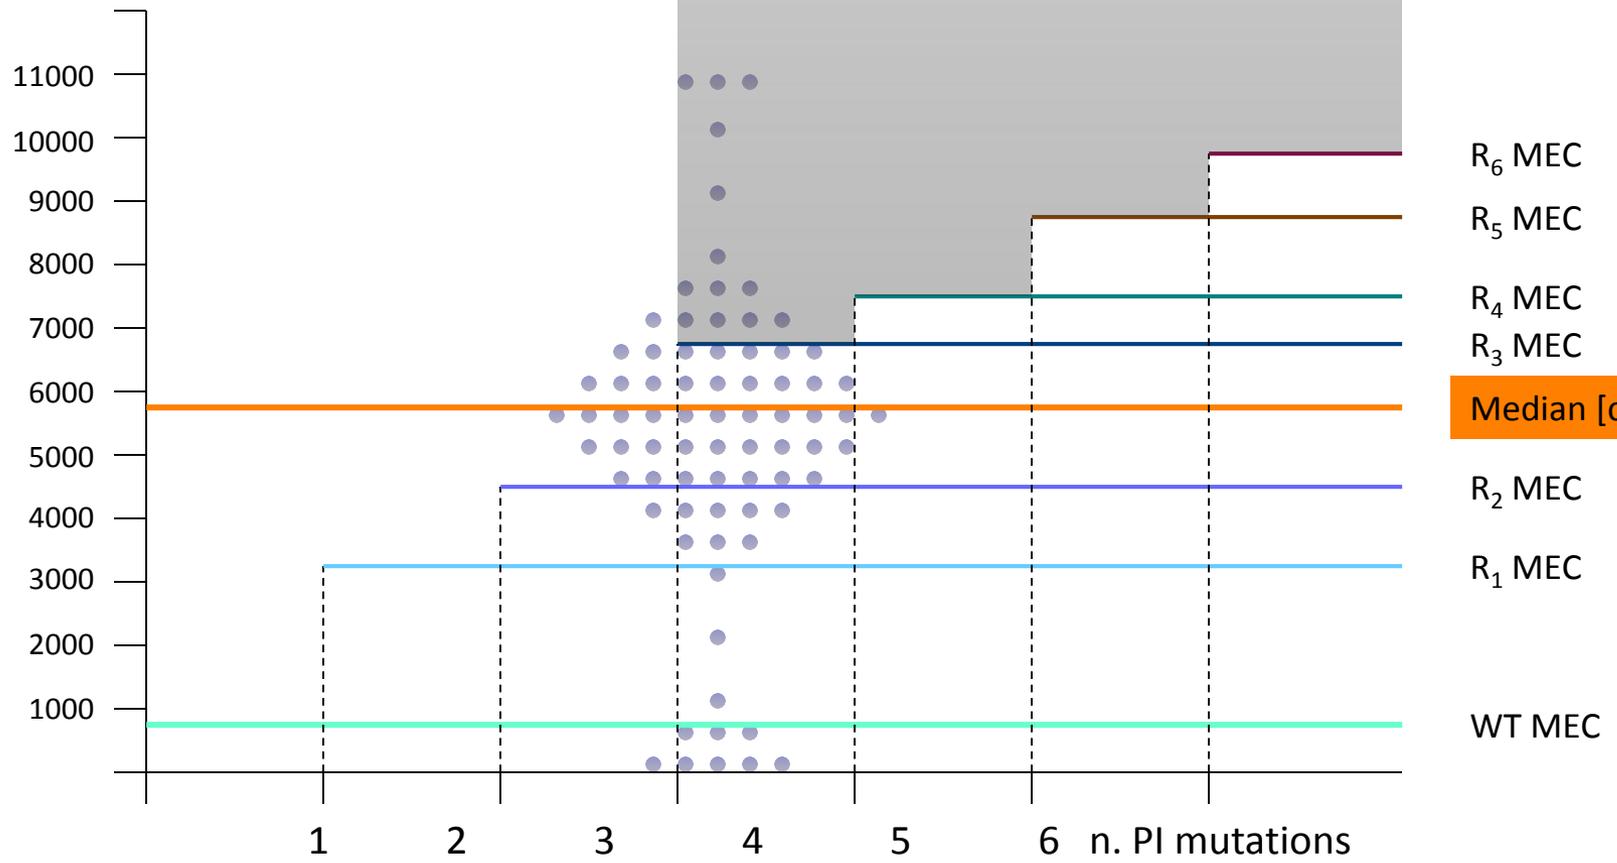

In studies on PI-experienced pts. IQ has been repeatedly found to have a higher predictive value than drug [c] or sensitivity testing taken alone

Unusual dosing:

- Superboosting
- Increased PI dose
- Both

[c] ng/mL
